Since two regression generates similar RMSE. Following principle of parsimony, we choose the simpler model with tree using 1SE principle. And the plot is shown below:

```
rpart.plot(rpart.fit2$finalModel)
```

Interpretation: The regression tree pruned by 1SE rule has size as 3. When log(cancer volume)(lcavol) is greater than 2.5, the log(prostate specific antigen) is predicted to be 3.8, which contains 22% of the training observations.

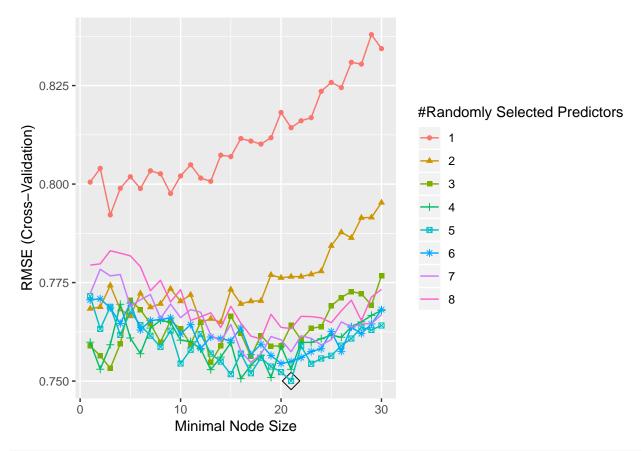

(c) Perform bagging and report the variable importance.

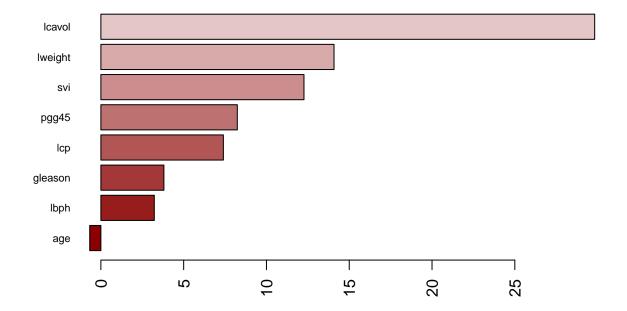

Based on the output, variable importance ranking: lcavol>lweight>svi>pgg45>lcp>gleason>lbph>age.

(d) Perform random forests and report the variable importance.

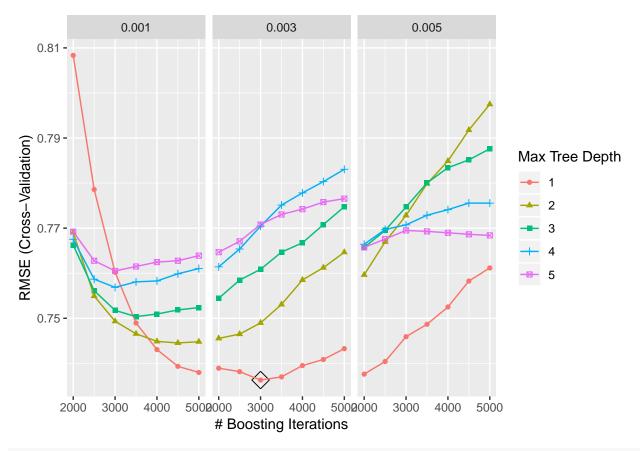

```
set.seed(1)

bwplot(resamp2, metric = "RMSE")
```

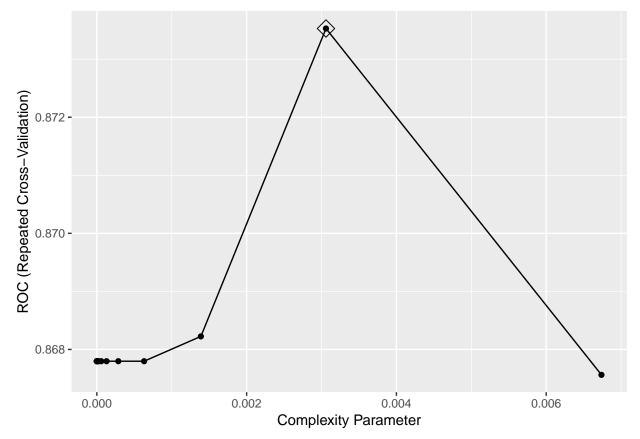

Based on the output, simple regression trees method including minimum CV error and 1SE principle methods generates model with larger RMSE than ensemble methods(bagging, random forest, boosting). And bagging being a special case of random forest selecting 8 predictors(mtry = 8) without tunning, violated principle of parsimony compared to random forest and boosting methods. Boosting generates model with smaller RMSE than randomForest. Hence, boosting model is most preferrable.

2. This problem involves the OJ data in the ISLR package. The data contains 1070 purchases where the customers either purchased Citrus Hill or Minute Maid Orange Juice. A number of characteristics of customers and products are recorded. Create a training set containing a random sample of 800 observations, and a test set containing the remaining observations. Use set.seed() for reproducible results. ## load data

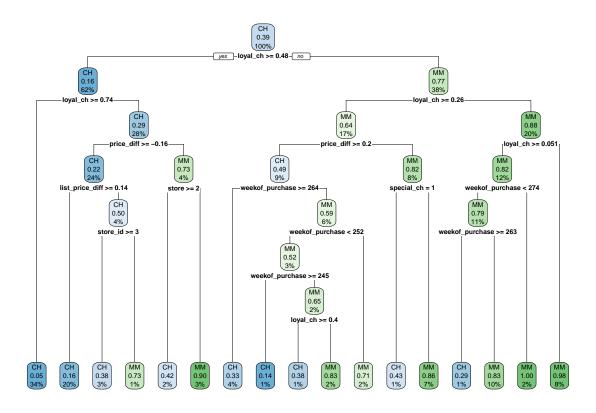

[1] 800 18

(a) Fit a classification tree to the training set, with Purchase as the response and the other variables as predictors. Use cross-validation to determine the tree size and create a plot of the final tree. Predict the response on the test data. What is the test classification error rate?

```
# optimal tree size is 17 with smallest CV error
rpart.fit_oj$finalModel$cptable
```

```
## CP nsplit rel error
## 1 0.525641026 0 1.0000000
```

[254] MM MM MM CH MM CH

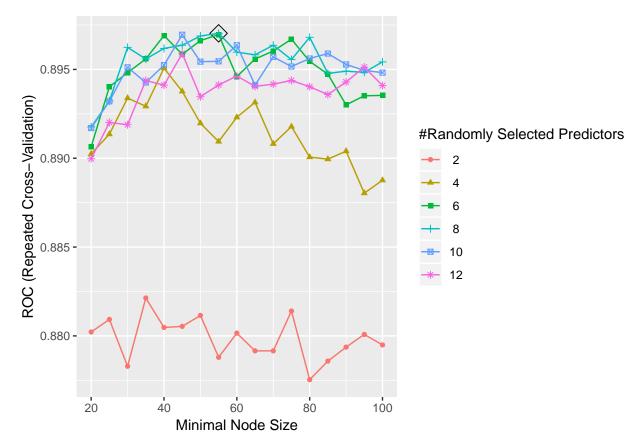

Levels: CH MM

```
# test classification error rate
1 - mean(test_data$purchase == pred)
```

[1] 0.2074074

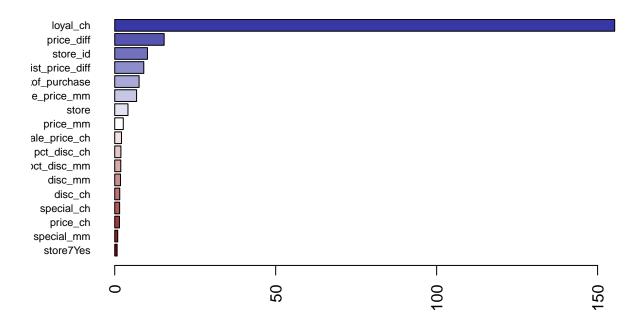

Hence, the optimal tree size is 17 and the test classification error rate is 0.207.

(b) Perform random forests on the training set and report variable importance. What is the test error rate?

```
# compare variable importance
barplot(sort(ranger::importance(rf.fit_oj$finalModel), decreasing = FALSE),
```

```
las = 2, horiz = TRUE, cex.names = 0.7,
col = colorRampPalette(colors = c("darkred","white","darkblue"))(19))
```

```
# predict on test data
pred2 = predict(rf.fit_oj, newdata = test_data,
            type = "raw");pred
##
